TITLE: The Working Equipment of Open-work Mining Excavators

PERIODICAL: Gornyy zhurnal, 1961, No. 5, pp. 40 - 44

TEXT: Open-work mining is concerned mostly with rocks and the mined masses are mainly loaded by bucket dredges. The Institut VNIIStroydormash Gosplana SSSR (All-Union Scientific Research Institute of Construction and Road Machinery of the State Planning Commission USSR) has fixed a standard series of open-work-mining excavators consisting of five types of various dimensions with a bucket of from 2 to 12  $m^3$  and a weight of from 80 to 480 t. These are to be designed and manufactured in the near future. While the mining of various soils has been sufficiently studied, the scooping of loose rocks has not yet been investigated sufficiently. After blasting, the rocks lie in stacked formation, the filling of the bucket being thus determined by entirely different factors than for the mining of soils in

the massif. The experimental study of the scooping of rocks by buckets conducted by the Institut gornogo dela Sibirskogo otdeleniya AN SSSR (Mining Institute of the Siberian Department of the AS USSR) and other institutions during the period 1948 to 1957, as well as the long design- and operational experience with bucket-loading vehicles gave the following results: the main conditions for reliable scooping of rocks are: 1) the penetration of the bucket into the material, the former progressing horizontally, and 2) the consecutive vertical turn of the bucket (with smallest possible radius). Scooping is most effective when the horizontal bucket movement, after reaching a certain initial depth of penetration into the material, is combined with the further turning of the bucket in the vertical plane. According to data by Professor N. G. Dombrovskiy (Ref. footnote on p. 41) the efficiency of the lifting buckets for the loading of rocks amounts to only 32 to 58% of that in soils. For this reason the bucket was replaced by a telescopic device with a shovel-shaped bucket. The Kovrovskiy ekskavatornyy zavod (Kovrov Excavator Plant) has designed the excavator of the type 9-6514 (E-6514) with telescopic equipment. It

was tested in 1959. The Institut gornogo dela AN KazSSR (Mining Institute of the AS Kazakhskaya SSR) elaborated a variant of a telescopic equipment for the excavator of the type E-504 (E-504). This equipment is similar to that used in the USA. In order to increase the efficiency of this equipment, the rigid connection of the bucket with the shaft should be abandoned and the shovel-shaped bucket should be made rotary, the radius of rotation having to be as small as possible. Two such variants are shown here in Figs. 2 and 3. They would considerably improve the excavators for the loading of loose rock in open-work mining and on construction sites. The IGD SO AN SSSR (IGD SO AN USSR) jointly with the Institut Sibgiprogormash (Sibgiprogormash Institute) is at present laying down the standard dimensions for the telescopic equipment for the bucket excavators used mostly. There are 3 figures, 1 table, and 4 Soviet references.

SOV/21-58-11-8/28

TITLE: An Experimental Investigation of Hydraulic Resistance in a Concrete Channel (Trough) With a Cement Floor (Eksperimental'noye issledovaniye gidravlicheskogo soprotivleniya v betonnom kanale (lotke) s zheleznennoy poverkhnost'yu)

PERIODICAL: Dopovidi Akademii nauk Ukrains'koi RSR, 1958, Nr 11,  
pp 1186-1189 (USSR)

ABSTRACT: The method of calculating concrete water conduits, which was developed by A.P. Zegzhda [Ref 1], was based on the assumption that concrete surfaces have roughness of the granular type and that the hydraulic resistance of these surfaces obeys the laws derived by Nikuradze for a granular roughness of sand. The author carried out experiments to determine the hydraulic resistance in a trough with a cement-floor concrete surface and glass walls. These experimental investigations showed that the hydraulic resistance of such surfaces do not follow the laws of Nikuradze - Zegzhda. On the basis of the analysis of resistances in tubes and troughs made of various materials, the author came to the conclusion that hydraulic resistances in a smooth channel depend on the material of the surface.

TITLE: The Coefficient of Roughness of Earth Channels With Large Cross-sections (Koeffitsiyent sherokovatosti zemlyanykh kanalov bol'shogo secheniya)

PERIODICAL: Izv. In-ta gidrol. i gidrotekhn. AN UkrSSR, 1955, Vol 12, pp 28-45

ABSTRACT: From an analysis of the expressions for the velocity factor C and their verification by means of test data on the resistance losses of silt-free channels with large cross-sections, the Author arrives at the following conclusions: 1) The N.N.Pavlovskiy formula, which is substantiated by experimental data and which is becoming more and more widely adopted in applied hydraulics computations, must continue to be considered as a fundamental tool in the determination of the velocity factor C; 2) The I.I.AgroSkin formulas and the abbreviated Ganguillet-Kutter formula yield satisfactory numerical results for earth channels; their values for the velocity factor C do not deviate more than 5% from those given by the N. N.Pavlovskiy formula; 3) The magnitude of the velocity factor C

Card 1/2

124-1957-1-501

The Coefficient of Roughness of Earth Channels (cont.)

given by the full Ganguillet-Kutter formula deviates by 15-35% from that obtained from the N.N. Pavlovskiy formula. The Authors used the results of investigations by the Institut gidrologii i hidrotekhniki AN USSR (Institute of Hydrology and Hydraulic Engineering, UkrSSR Academy of Sciences), the Institut sooruzheniy AN UzSSR (Institute of Structures, UzSSR Academy of Sciences), and of L.S.Kuskov and I.N.Dymen performed on the "Moscow" canal. They evolved and recommend a new scale for the coefficient of roughness for earth channels with large sections and with a 20% paved surface reinforcement of the wetted perimeter; the new scale is suitable for use of the Pavlovskiy formula for C. The full Ganguillet-Kutter formula mentioned in the paper is mistakenly referred to as the G.A.Dzhimsheli formula; also, the coefficient 0.0155 in that equation is erroneously shown as 0.155.

TITLE: A simple intervalograph model

SOURCE: Byul. eksper. biologii i meditsiny\*, v. 57, no. 2, 1964,  
121-123

TOPIC TAGS: intervalograph, intervalograph simple model, blood  
circulation rate

ABSTRACT: A simple intervalograph model for measuring blood circulation rate by drops per minute is described. The device consists of a vessel connected by an air pipe to a chamber which is connected to a recording stylus. Compressed air coming from the vessel inflates the chamber and raises the stylus. An electromagnetically operated valve located between the chamber and stylus normally remains closed, and opens only when an electric signal is induced by a falling drop. With the valve open, air escapes from the chamber and the stylus drops. The recorded amplitude is directly proportional to the time interval between two falling drops and is inversely

TITLE: Investigation of the biomechanics of running in dogs

SOURCE: Biofizika, v. 10, no. 4, 1965, 665-672

TOPIC TAGS: motion mechanics, animal physiology

ABSTRACT: The authors investigated the kinematics (trajectory of hinge joints, phases of support and transfer of extremity) of dogs running on a threadmill at speeds ranging from 1 1/2 to 11 km/hour. The cycle of each joint was found to have an area (transfer phase) whose trajectory is virtually constant regardless of the speed at which the animal runs. Shifting by the animal in relation to the support during the running is likewise little affected by the speed. The coordination of movements in all the main joints of an extremity is more or less constant at all rates. However, the coordination between the symmetrical extremities and the antero-posterior relations do vary with the speed of running. There are standard

Card 1/2

62518-65

ACCESSION NR: AP5018000

elements and elements varying with the speed in the kinematic picture. Only two parameters are significantly dependent on the speed. It is biomechanically impossible to run at different speeds with a change in fewer parameters. "The authors are grateful to I. M. Gol'fand, B. S. Gurfinkel', I. I. Pyatetskiy-Shapiro, and M. L. Tsatlin for their interest in this work and for valuable advice." Orig. art. has 5 figures.

TITLE: The development of a masticated rubber on a polyvinylchloride base for shielding against radioactive substances

SOURCE: Zashchitnye pokrytiya v atomnoy tekhnike (Shielding in nuclear engineering); sbornik statey. Moscow, Gosatomizdat, 1963, 25-34

TOPIC TAGS: nuclear engineering, masticated rubber, nuclear shielding, radioactivity, polyvinylchloride polymer, radioactive shielding, radioactive contamination, residual activity, 57-40 rubber

ABSTRACT: It is pointed out that, of the industrial polymers produced at the present time, polyvinylchloride is, in terms of its inexpensiveness and mechanical and technological properties, the best material to serve as a base for shielding in nuclear engineering. The authors tested many masticated rubber materials on polyvinylchloride resin bases in terms of their sorption-desorption characteristic as a function of the type of polyvinylchloride resin, processing conditions and the presence of different components which provide for

Cord 1/3

ACCESSION NR: AT4016991

the required physico-mechanical and technological properties of the material. (By "sorption-desorption properties" the authors mean the ability of the material to absorb radioactivity and to be washed free of these radioactive substances through the effect of special cleansing solutions; the sorption-desorption characteristic is expressed by the residual activity of the material in percentages of the original contamination). The results of these tests are discussed. The optimal solution of the problem of developing a material to meet the specific operating requirements involved in working with radioactive substances was found in an entirely new principle of composition. This principle consists of the introduction into the composition of specially selected admixtures of hydrophobic substances which separate out on the surface of the masticated rubber in the form of a thin layer. The research conducted along these lines by the authors led to the possibility of developing on the basis of the most accessible polymer - polyvinylchloride - a new type of shielding material, called masticated rubber formula 57-40 and 80. This material is a thermoplastic and its physical and mechanical properties depend to a large degree on the temperature (its tensile strength, for example, changes with increasing temperature) and, for this reason, the formula use must be limited to a temperature interval of from 0 to 50C. The effect of the radiation dosage on the strength

Card 2/3

ACCESSION NR: AT4016991

of the masticated rubber and on its elongation are discussed along with certain other specific characteristics of the material. The authors point out that formula 57-40 and 80 masticated rubber has successfully undergone tests under different conditions and is presently being widely used as a shielding material in radiochemical laboratories and at atomic power centrals. Easily deactivated and possessed of extremely high resistance to wear, this shielding material, produced in thicknesses of 2 and 3 mm, is particularly suited to continuous covering of floors and, produced in thicknesses of 0.3, 0.5 and 0.7 mm, may be utilized as a wall covering. The masticated rubber is available in colors of brown, orange, blue and white. "L.I. Kuz'mina and L.G. Danilova of the Okhtinskii khimkombinat (Okhtinsk Chemical Works) took part in the work."
